

1. US CRUDE OIL INVENTORIES (YOY)

Oil inventories go through a cycle every 3 to 4 years, and increasing inventories indicate weakening fundamentals for crude oil. There is a negative correlation between the year-over-year growth rate of oil inventories and the oil price.

2. US CRUDE OIL INVENTORIES (DIVIDED BY 5-YEAR AVG) VS. OIL PRICE

The blue line represents EIA crude oil inventories divided by their 5-year average. This metric provides a more precise reflection of inventory changes relative to the long-term average, without being skewed by low base periods. Notably, this metric exhibits a clear negative correlation with oil prices.

3. US CRUDE OIL SUPPLY & DEMAND

The EIA releases data on daily petroleum product consumption and field production in its weekly report. Crude oil demand tends to fluctuate but generally rises in late spring to summer (mainly from gasoline for transportation) and late fall to winter (primarily driven by heating fuels).

4. GEOPOLITICAL RISK INDEX VS OIL PRICE

The Geopolitical Risk Index (GPR) was compiled by US Fed economists Dario Caldara and Matteo Iacoviello. This index is constructed based on the number of newspaper articles mentioning certain keywords related to geopolitical tension. The index spiked around WWI and WWII, the Korean War, the Cuban Missile Crisis, 9/11, and the Iraq War, thus showing correlation to periods of sharp oil price fluctuations.

5. CRUDE OIL COT INDEX

COT Index = Large Non-Commercial (Speculator) Net Position - Large Commercial (Hedger) Net Position

The COT index indicates the bullish/bearish sentiment of large traders. When the index rises, it signifies that large investors are bullish about the crude oil market.

6. US DOLLAR INDEX VS OIL PRICE

Since oil futures prices are denominated in US dollars, there is usually a negative correlation between the US Dollar Index and oil prices.

7. US CRUDE OIL RIG COUNT VS OIL PRICE

Baker Hughes releases the drilling rig count of active rigs in the US on the last day of the work week. Rig counts can reflect drillers' expectations regarding oil prices, as they tend to rise when drillers anticipate an increase in oil prices.

8. US OIL INVENTORIES VS. REFINERY UTILIZATION RATE

The refinery utilization rate is an indicator of future fuel demand. When refineries are optimistic about future demand, they increase capacity utilization, resulting in a decline in oil inventories.

9. WORLD PETRO & OTHER FUEL PRODUCTION & CONSUMPTION ESTIMATES

This chart shows the current and projected supply and demand for petroleum and other liquid fuels from the monthly Short-Term Energy Outlook (STEO) report by the US Energy Information Administration (EIA). The fuels include crude oil, gas, diesel, and aviation fuel. When supply outgrows demand, oil prices could fall.

Note: Figures in the chart are in million barrels per day (bpd).

10.MM CRUDE OIL FUNDAMENTAL INDEX

The MM Fundamental Index (MMFI) for crude oil is an integral index created by MacroMicro. An upward movement of the index indicates positive fundamentals for crude oil.

The components of this index include US crude oil inventories (YoY), the Crude Oil COT Index, US gasoline and distillate fuel inventories among others. The weight of each component is adjusted based on the latest market conditions.
